

DESCRIPTION

NOVEL ETHYLENEDIAMINE DERIVATIVES.

TECHNICAL FIELD

5 The present invention relates to novel compounds
which inhibit activated blood coagulation factor X
(hereinafter abbreviated as "FXa") to exhibit a potent
anticoagulant effect and can be orally administered, and
anticoagulants or preventives and/or therapeutic agents
10 for thrombosis or embolism, which comprise the compound
as an active ingredient.

BACKGROUND ART

15 In unstable angina, cerebral infarction, cerebral
embolism, myocardial infarction, pulmonary infarction,
pulmonary embolism, Buerger's disease, deep venous
thrombosis, disseminated intravascular coagulation
syndrome, thrombus formation after valve replacement,
reocclusion after angioplasty and thrombus formation
20 during extracorporeal circulation, a hypercoagulable
state is a pivotal factor. Therefore, there is a demand
for development of excellent anticoagulants which have
good dose responsiveness, long duration, low risk of
hemorrhage and little side effects and fast onset of
25 sufficient effects even by oral administration
(Thrombosis Research, Vol. 68, pp. 507-512, 1992).

Based on the research of anticoagulants worked

through various mechanism of action, it is suggested that FXa inhibitors are promising anticoagulants. A blood coagulation system comprises a series of reactions that a great amount of thrombin is produced through an amplification process by multi-stage enzyme reactions to form insoluble fibrin. In an endogenous system, activated factor IX activates factor X on a phospholipid membrane in the presence of activated factor VIII and calcium ions after multi-stage reactions subsequent to activation of a contact factor. In an exogenous system, activated factor VII activates factor X in the presence of a tissue factor. More specifically, the activation of the factor X into FXa in the coagulation system is a crucial reaction in the formation of thrombin. The activated factor X (FXa) limitedly decomposes prothrombin to produce thrombin in the both systems. Since the produced thrombin activates coagulation factors in the upper stream, the formation of thrombin is more amplified. As described above, since the coagulation system in the upper stream of FXa is divided into the endogenous system and the exogenous system, production of FXa cannot be sufficiently inhibited by inhibiting enzymes in the coagulation system in the upper stream of FXa, leading to production of thrombin. Since the coagulation system comprises self-amplification reactions, inhibition of the coagulation system can be more efficiently achieved by inhibiting

FXa in the upper stream of thrombin than the inhibition of the produced thrombin (Thrombosis Research, Vol. 15, pp. 617-629, 1979). Another excellent point of FXa inhibitors is a great difference between an effective dose in a thrombosis model and a dose elongating bleeding time in an experimental hemorrhagic model. From this experimental result, FXa inhibitors are considered to be anticoagulants having low risk of hemorrhage.

Various compounds have been reported as FXa inhibitors. It is known that antithrombin III and antithrombin III dependent pentasaccharides are unable to inhibit prothrombinase complexes in general which play a practical role in the thrombus formation in a living body (Thrombosis Research, Vol. 68, pp. 507-512, 1992; Journal of Clinical Investigation, Vol. 71, pp. 1383-1389, 1983; Mebio, Vol. 14, the August number, pp. 92-97). In addition, they do not exhibit effectiveness when orally administered. Tick anticoagulant peptide (TAP) (Science, Vol. 248, pp. 593-596, 1990) and antistasin (AST) (Journal of Biological Chemistry, Vol. 263, pp. 10162-10167, 1988) isolated from bloodsuckers such as mites and leeches also inhibit Fxa and exhibit anti-thrombotic effects against venous thrombosis and arterial thrombosis. However, these compounds are high-molecular weight peptides and unavailable in oral administration. As described above, development of antithrombin III independent low-molecular weight FXa

inhibitors which directly inhibit coagulation factors has been conducted.

DISCLOSURE OF THE INVENTION

5 It is therefore an object of the present invention to provide a novel compound which has a potent FXa-inhibiting effect and exhibits an anti-thrombotic effect quickly, sufficiently and persistently by oral administration.

10 The present inventors have investigated synthesis and pharmacological effects of novel FXa inhibitors. As a result, ethylenediamine derivatives or salts thereof, and solvates and N-oxides thereof, which exhibit potent FXa-inhibiting effect and anticoagulant effect, have
15 been found. It has also been found that these compounds promptly, persistently and potently inhibit FXa and exhibit potent anticoagulant effect and anti-thrombotic effect even by oral administration, and are hence useful as preventives and therapeutic agents for various
20 diseases based on thromboembolism, thus leading to completion of the present invention.

5 The preparation process of the ethylenediamine derivatives (1) of the present invention will next be described, but the present invention is not limited thereto.

[Preparation Process 1]

An ethylenediamine derivative, which is a compound

(1) in which T^1 represents a group $-\text{CO}-\text{CO}-\text{N}(\text{R}')-$ (in which, R' has the same meaning as described above) or salt thereof, a solvate thereof or an N-oxide thereof can be prepared in accordance with, for example, the following process:

wherein Q^1 , Q^2 , Q^3 , Q^4 , R^1 , R^2 and R' have the same meanings as described above, and T^1 represents a group $-\text{CO}-\text{CO}-\text{N}(\text{R}')-$ (in which, R' has the same meaning as described above).

Compound (4) is prepared by inducing carboxylic acid (3) or salt thereof into the corresponding mixed acid anhydride, acid halide, activated ester or the like and reacting the resulting product with diamine (2). The compound (1) of the present invention can be prepared by reacting the resulting compound (4) with carboxylic acid (5) or salt thereof under similar conditions. In the above-described reaction of each step, reagents and conditions ordinarily used in peptide synthesis may be

applied. The mixed acid anhydride can be prepared, for example, by reacting a chloroformate such as ethyl chloroformate or isobutyl chloroformate with carboxylic acid (3) or salt thereof in the presence of a base. The acid halide can be prepared by treating carboxylic acid (3) or salt thereof with an acid halide such as thionyl chloride or oxalyl chloride. Although the activated ester includes various kinds of esters, they can be prepared for example by reacting a phenol such as p-nitrophenol, N-hydroxybenzotriazole, or N-hydroxysuccinimide with carboxylic acid (3) or salt thereof while using a condensing agent such as N,N'-dicyclohexylcarbodiimide or 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide hydrochloride. The activated ester can also be prepared by the reaction of carboxylic acid (3) or salt thereof with pentafluorophenyl trifluoroacetate or the like, reaction of carboxylic acid (3) or salt thereof with 1-benzotriazolyloxytripyrrolidinophosphonium hexafluorophosphate, reaction of carboxylic acid (3) with diethyl cyanophosphonate (Shioiri method), reaction of carboxylic acid (3) with triphenylphosphine and 2,2'-dipyridyl disulfide (Mukaiyama method) or the like. The mixed acid anhydride, acid halide or activated ester of carboxylic acid (3) thus obtained may be reacted with diamine (2) at -78°C to 150°C in the presence of a proper base in an inert solvent, whereby compound (4) can be

prepared. The compound (1) of the present invention can be prepared by reacting the compound (4) thus obtained with a mixed acid anhydride, acid halide or activated ester of carboxylic acid (5) under similar conditions.

5 The reagents and reaction conditions in the reaction of compound (4) with carboxylic acid (5) are similar to those in the reaction of diamine (2) with carboxylic acid (3).

Specific examples of the base to be used in each
10 of the above-described steps may include carbonates of an alkali metal or alkaline earth metal, alkali metal alkoxides, and alkali metal hydroxides or hydrides such as sodium carbonate, potassium carbonate, sodium ethoxide, potassium butoxide, sodium hydroxide,
15 potassium hydroxide, sodium hydride and potassium hydride; organic metal bases typified by alkyl lithium such as n-butyl lithium, and dialkylamino lithium such as lithium diisopropylamide; organic metal bases such as bis(silyl)amine, for example, lithium
20 bis(trimethylsilyl)amide; and organic bases such as pyridine, 2,6-lutidine, collidine, 4-dimethylaminopyridine, triethylamine, N-methylmorpholine, diisopropylethylamine and diazabicyclo[5.4.0]undec-7-ene (DBU).

25 Examples of the inert solvent to be used in this reaction include alkyl halide solvents such as dichloromethane, chloroform and carbon tetrachloride,

ether solvents such as tetrahydrofuran, 1,2-dimethoxyethane and dioxane, aromatic solvents such as benzene and toluene, and amide solvents such as N,N-dimethylformamide, N,N-dimethylacetamide and N-methylpyrrolidin-2-one. In addition to these solvents, a sulfoxide solvent such as dimethyl sulfoxide or sulfolane, a ketone solvent such as acetone or methyl ethyl ketone may be used in some cases.

Carboxylic acid (3) or salt thereof, and carboxylic acid (5) or salt thereof can each be prepared by the hydrolysis of the corresponding ester compound. In the case of a methyl or ethyl ester, carboxylic acid can be prepared by hydrolyzing the ester with a proper base such as hydroxide of an alkali metal, for example, lithium hydroxide, sodium hydroxide or potassium hydroxide. In the case of a tert-butyl ester, carboxylic acid can be prepared by treating it with trifluoroacetic acid, hydrochloric acid or the like.

The invention compound sometimes has an optical isomer derived from an asymmetric carbon. Such an optically active substance can be prepared from optically active diamine (2) which is commercially available or available by using the known process (for example, Synth. Commun. 22, 883(1992)). It can also be prepared by fractionally crystallizing the racemic compound using an optically active amine or acid to form a salt, or by separating it through column

chromatography using an optically active carrier.

[Preparation Process 2]

 described above).

Compound (1) of the present invention can be
 prepared by dissolving or suspending sodium thiosulfate

(13) and compound (9) obtained in the pathway as described in Preparation Process 2 in a solvent and then heating the resulting solution or suspension. A 4N hydrochloric acid dioxane solution (10.0 ml) was added to a dioxane (15.0 ml) solution of the compound (414 mg) obtained in Referential Example 430. The resulting mixture was stirred at room temperature for 7 days. The insoluble matter thus precipitated was collected by filtration, washed with dioxane and dried, whereby the title compound (378 mg) was obtained.

[Test 1] Determination of human FXa-inhibiting effect (IC_{50} value):

A 5% DMSO solution (10 μl) of each test compound, the concentrations of which had been suitably set stepwise, and Tris buffer (100 mM Tris, 200 mM potassium chloride, 0.2% BSA, pH 7.4) (40 μl) and 0.0625 U/ml human FXa (Enzyme Research Laboratories, Inc., dissolved in and diluted with Tris buffer) (10 μl) were put in each of the wells of a 96-well microplate. A 750 μM aqueous solution (40 μl) of S-2222 (Chromogenix Co.) was added. Absorbance at 405 nm was measured for 10 minutes at room temperature

to determine an increase in absorbance ($\Delta OD/min$). As a control, Tris buffer was used in place of the test compound.

The percent inhibition (%) calculated using the following equation at the final concentration of the test compound and the final concentration of the test compound were plotted on the ordinate and abscissa of logarithmic probability paper, respectively, to determine the 50 % inhibition concentration (IC_{50} value).

$$\text{Percent inhibition (\%)} = [1 - (\Delta OD/min \text{ of test compound}) \div (\Delta OD/min \text{ of control})] \times 100$$

From the test results that IC_{50} of the compound of Example 2 is 7.1 nM, that of the compound of Example 26 is 2.4 nM, that of the compound of Example 37 is 1.5 nM, that of the compound of Example 38 is 0.81 nM, that of the compound of Example 39 is 0.86 nM, that of the compound of Example 40 is 1.3 nM, that of the compound of Example 62 is 1.8 nM and that of the compound of Example 66 is 2.0 nM, it has been elucidated that the compounds according to the invention have a potent FXa inhibitory action.
